### Footnotes: Specifications are subject to change without notice

- Assembled in a state-of-the-art facility. Andor's UltraVac™ vacuum process combines a permanent hermetic vacuum seal (no o-rings), with a stringent protocol and proprietary materials to minimize outgassing. Outgassing is the release of trapped gases that would otherwise degrade cooling performance and potentially cause sensor failure.
- Figures are typical unless otherwise stated.
- Edge pixels may exhibit a partial response.
- Minimum temperatures listed are typical values with ambient temperature of 25°C.
- Based on a Horizontal Pixel Readout of 100 kHz and a vertical pixel shift of 8 μs.
- System Readout Noise is for the entire system. It is a combination of CCD readout noise and A/D noise. Measurement is for Single Pixel readout with the CCD at a temperature of -50°C (BR-DD models tested at -80°C) and minimum exposure time under dark conditions. Noise is measured at the highest available pre-amplifier gain for each speed.
- Linearity is measured from a plot of counts vs exposure time under constant photon flux up to the saturation point of the system.
- Vertical speeds are software selectable. All sensors are designed to give optimum Charge Transfer Efficiency (CTE) at 16 μs vertical pixel shift, some decrease in CTE may be observed at faster shift speeds.
- The graph shows typical dark current level as a function of temperature. The dark current measurement is averaged over the CCD area excluding any regions of blemishes.
- Quantum efficiency of the sensor as supplied by the sensor manufacturer.
